Random Number Generator with Elementary Cellular Automata in Matlab

Donald Bertucci*

Abstract: In Matlab, I implemented a random number generator that uniformly generates numbers between 0 and 1. I created the `rand_eca` function to sample from a known simple yet chaotic system: Elementary Cellular Automata rule 30. I then showed that my `rand_eca` function is likely a uniform random distribution by using the χ^2 test. Finally, I implemented the `uniform_to_pdf` function to map the uniform `rand_eca` to any another distribution (like standard normal). All the Matlab code is open source at https://github.com/xnought/rand-eca and shown in the Appendix starting from Appendix A.

1 Introduction

Elementary Cellular Automata (ECA) have extremely simple rules that transform the current state (a 1D list of on and off cells) to the next state, and from that state to the next state, and so on [3, 4, 5]. A simple example is shown on the left in Figure 1 for one time step. The simplicity might lead you to believe the system is predictable, but you would be wrong. Some ECA update rules, like rule 30, lead to emerging complex patterns that are unpredictable and chaotic (see Figure 1 on the right) [3, 4, 5].

To be specific, at the current time step t you could not predict the state n steps into the future $t + n$ without computing all the steps in between (computationally irreducable)[3, 4, 5]. There are no shortcuts or linear patterns: you have to manually apply the rule n times to get to $t + n$ [3, 4, 5]. Since the more unpredictable a system is, the more seemingly random it is, I created a Matlab random uniform function from rule 30 which I called `rand_eca`.

Figure 1: On the left, I transformed the 1D list of on (black) and off (white) cells from a **Start state** to the **Next state** with rule 30. On the right, I applied rule 30 for hundreds of iterations starting from a 129 cell wide start state with 1 black cell in the middle.

*Oregon State University, donnybertucci.com

Figure 2: Running ECA rule 30 for 512 generations from the starting state of 513 cells with 1 in the middle. Here I only visualize row 257 to 513. On the right I show a zoomed-in 13 cell long chunk from a column converted to decimal.

2   Implementation of `rand_eca`

In Matlab, I implemented the `rand_eca` function (Appendix F) in two steps: running generations of ECA with rule 30 (Section 2.1) and converting the ECA output to numbers between 0 and 1 (Section 2.2).

2.1   Generating Elementary Cellular Automata

Given a starting state as a one-dimensional list of 1s (black) and 0s (white), I first implemented a function to produce the next state. The function `rule30(vec3)` (Appendix A) takes a vector with three cells to produce the ith cell in the next state using rule 30. The transformation shown on the top left in Figure 1 is equivalent to p `xor` (q `or` r) where p, q, r are the three bits denoting the three cells [3].

Next, I slid the `rule30` function across the 1D state to produce the ith cell in the next state with the function `next_state_rule30(current_state)` (Appendix B) as shown in the bottom left in Figure 1.

To produce many iterations of rule 30, I implemented the `iterate_rule30(start_state, n_iterations)` function (Appendix C) which produced the visuals on the right in Figure 1. All this function does is apply the `next_state_rule30` to the current state to produce the next state. Then it uses that next state to produce the state after that, and so on for `n_iterations`. To visualize the output, I created a function called `visualize_rule30(start_state, n_iterations, visualize_from_i)` (Appendix D) which simply runs `iterate_rule30` and outputs a Matlab figure from rows `visualize_from_i` till the last row. For example, `visualize_rule30([zeros(1, 256) 1 zeros(1, 256)], 512, 257)` produced the Figure 2 and `visualize_rule30([zeros(1, 64) 1 zeros(1, 64)], 200, 1)` produced the Figure 1.

2.2   Extracting Numbers

As shown in Figure 2 on the right, I can take a single column from the generations of rule 30 and and convert the bits to a decimal number between $[0, 1)$. In my case, I wanted 13 bits for each number, so I can take a 13 cell long column from the generations and interpret the white cells as 0 and the black cells as 1. I can convert from base 2 to base 10 as

$$d(b) = b_1 \cdot 2^0 + b_2 \cdot 2^1 + \cdots + b_n \cdot 2^{n-1} \tag{2.1}$$

where b_i is the bit at index i in a bit string and n is the total number of bits in that bit string.

Then, to force the decimal d into a fraction value, I'll divide the representation by the largest possible decimal of all $1s$ like $11\ldots1$ which is just $2^n - 1$ in decimal (since 0 is all $00\ldots0$ we subtract 1 from 2^n possible combinations). Because I want the fractional decimal to never be 1 itself, I'll add 1 to the divisor as $2^n - 1 + 1 = 2^n$. Simplifying the normalized expression I get

$$f(b) = \frac{d(b)}{d(11\ldots1) + 1} = \frac{b_1 \cdot 2^0 + b_2 \cdot 2^1 + \cdots + b_n \cdot 2^{n-1}}{(2^n - 1) + 1}$$
$$= \frac{b_1 \cdot 2^0}{2^n} + \frac{b_2 \cdot 2^1}{2^n} + \cdots + \frac{b_n \cdot 2^{n-1}}{2^n}$$
$$f(b) = b_1 \cdot 2^{-n} + b_2 \cdot 2^{-n-1} + \cdots + b_n \cdot 2^{-1}. \tag{2.2}$$

It's not difficult to see that the bounds of (2.2) is $[0, 1)$ for finite length bit strings.

In Matlab, I implemented the function `bits_to_fractions(bits, n, bits_per_number)` (Appendix E) which converts a bit string into a fraction. This function iterates in a chunk size of `bits_per_number` and converts each bit string into a fraction. This will be how I can convert a very long column from Figure 2 into `n` different fractions.

2.3 Putting the pieces together for `rand_eca`

I combined the last two sections to convert every column of a rule 30 ECA generation into numbers between $[0, 1)$.

Others have also extracted the ECA columns in the past. For example, when extracting the middle column only, the middle column has been shown to be aperiodic and therefore good for random number generation [1]. For `rand_eca`, I instead extract every single column, not just the middle column, to speed up the computation when producing large amounts of random numbers.

The final function is called `rand_eca(rows, columns)` (Appendix F) where you can generate a matrix of shape (rows, columns) of random uniform values. In `rand_eca`, I started from a starting state of 512 zeros on the left, a single 1, and 512 zeros on the right (in total 1025 cells). I then warmed up the starting state by first iterating 512 times and taking the last state as the new starting state. This warmup essentially turns the starting pyramid (like in Figure 1) to completely populated (like in Figure 2). This warmup initialization is done in the `rng_eca(offset)` function (Appendix H), which is also how you reseed the `rand_eca` for reproducible results.

Within `rand_eca`, I iterated enough ECA generations so that I could generate `rows` times `columns` amount of random numbers. I wanted a precision of 13 bits to correspond to a single random number. This meant I needed to generate $13 \cdot$ `rows` $\cdot$ `columns` bits in total, and that I needed to iterate $\lceil (13 \cdot$ `rows` $\cdot$ `columns`$)/1025 \rceil$ generations (divided by 1025 because I extract every column from a 1025 cell wide ECA states). I also chunked over the number of iterations to drastically save memory, but I'll leave the reader to the Matlab calculations in Appendix G.

After iterating, I could simply apply the `bits_to_fractions` function over all the ECA columns to generate the decimal numbers. Finally, the last state generated from `rand_eca` becomes the start state for the next function call later on. Again, please see Appendix F and Appendix H for the exact implementation in Matlab.

To give you one example of running `rand_eca`, I ran `rand_eca(100000, 1)` to produce a column vector with a hundred thousand random numbers as shown on the very right in Figure 3 in a histogram.

3 Test Compared to Random Uniform

Just to eye-ball how good `rand_eca` is, I can plot a histogram of generated numbers and see how well I approach a uniform distribution. In Figure 3, as I increase N generated numbers by a factor of 10 each time, I approach what appears to be a uniform distribution.
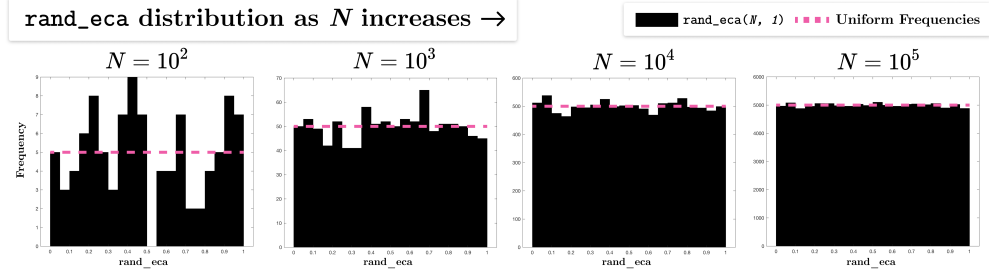

3

Figure 3: As I increase the numbers generated N, `rand_eca` approaches a uniform distribution. Each histogram has 20 bins/bars and `rand_eca` started from the same seed `rng_eca(0)` each time.

For a more rigorous test, I'll use the χ^2 test to evaluate whether `rand_eca` samples from a random uniform distribution. At large enough $N = 10^5$, given a null hypothesis that `rand_eca` for $n = 20$ bins has uniform counts at a $\alpha = 0.05$ significance level, I computed χ^2 with $n - 1 = 20 - 1 = 19$ degrees of freedom.

First I computed the test using the observed bin counts O_i from `rand_eca` compared to the uniform expected bin counts (equal frequency) of E as

$$\sum_{i=1}^{n} \frac{(O_i - E)^2}{E} \tag{3.1}$$

where n is the total number of bins and i refers to the ith bin index. I implemented (3.1) as the function `chi_squared_critical_value(data, bins)` (Appendix I). And since (3.1) is distributed like a χ^2 distribution with $n-1$ degrees of freedom, at a significance level of $\alpha = 0.05$, I can compare (3.1) to the theoretical critical value of 30.143 (area to the right of 30.143 is 0.05). If (3.1) is less than the critical value of 30.143, I will fail to reject the null hypothesis.

I observed that $\chi^2_{\alpha=0.05, df=19} = 15.2434$ with a p-value of 0.707 for `rand_eca` at $N = 10^5$ generated numbers. Since the observed test is less than the theoretical critical value, I do indeed fail to reject that `rand_eca` is distributed from a random uniform distribution. To compute these values I used the `chi_squared_test(data, bins)` function (Appendix L).

Just for reference, the built-in Matlab `rand` function which uses the Mersenne-Twister Algorithm [2] (starting from `rng(0)` seed) for the same configuration above gets $\chi^2_{\alpha=0.05, df=19} = 23.8466$ with a p-value of 0.2021 which also passes the test, but is less evidence than the `rand_eca` function.

So for large enough N, I've shown that the `rand_eca` function can be interpreted as a random uniform distribution. Run the `paper_figures.mlx` to reproduce these tests for yourself.

4 Sampling Other Distributions

The `rand_eca` function can produce a uniform distribution, but cannot generate other important distributions. For example, If I wanted to sample from a standard normal distribution, I would have to symbolically invert the standard normal, then input my `rand_eca` values.

Instead, I numerically approximated the inverse mapping from uniform to a target distribution. For example see some transformations in Figure 4. I first started with a target probability density function g, like the standard normal, and mapped the areas to a uniform distribution.

Then, I divided up the target g between a region $[a, b]$ into n sections I'll notate as $x_1, x_2, \ldots, x_n$. Each rectangle then has a width of Δx (just $x_{i+1} - x_i$) and with a height of $g(x_i)$. For all rectangles, I computed the areas per rectangle as $a_i = \Delta x \cdot g(x_i)$. As the number of rectangles increases, the sum of the areas should approach 1 for a sensible region $[a, b]$.

Next, I divided up the uniform distribution into rectangles sized with areas a_i. Since the `rand_eca` is between 0 and 1, I can simply divide up the x axis into accumulating a_i as shown
Figure 4: With $N = 10^5$ random numbers from rand_eca, I mapped to other probability density functions: two normal distributions mixed, exponential with $\lambda = 1$, and $1/(\pi(1 + x^2))$ for each of the plots.

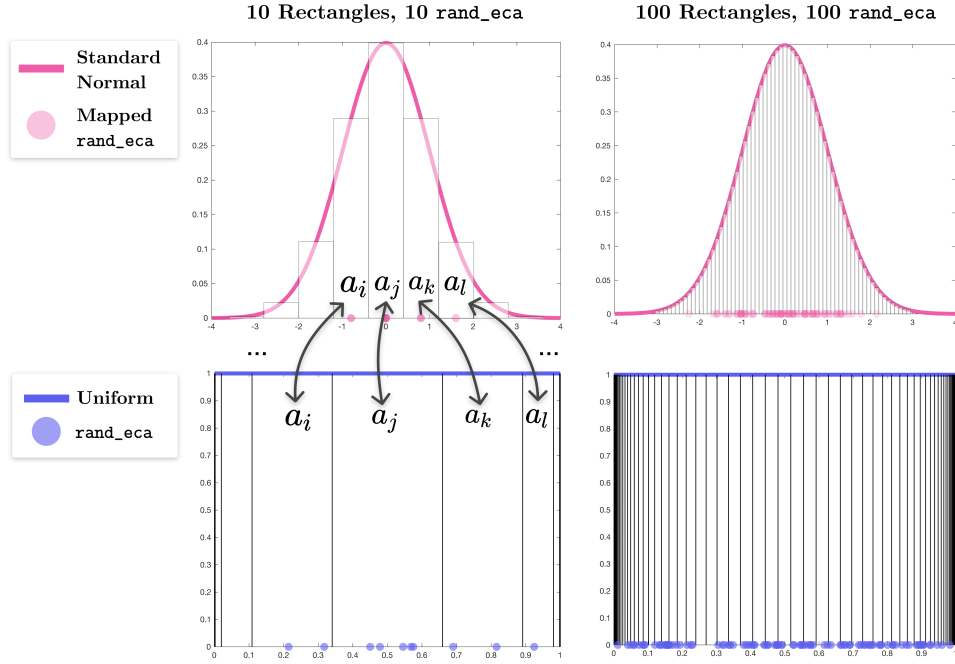

Figure 5: I can approximate the area (with rectangles) and map the areas back to uniform. As I increase the number of rectangles, the mapping gets more precise.

in Figure 5 on the bottom left. Now, I can take my random uniform sample from rand_eca, and figure out which ith rectangle each value fell into. Then map each value directly onto the corresponding ith target rectangle from g and use the x_i from g as the transformed number (see left Figure 5). As we increase the number of rectangle divisions, the more accurate the mapping becomes as shown on the right in Figure 5.

I provided the uniform_to_pdf(uniform, pdf, a, b, num_rectangles) (Appendix M) Matlab implementation where I map the random uniform numbers uniform to be distributed like the given pdf function. The approximation requires you to specify the bounds $[a, b]$ of the pdf and the precision with num_rectangles. For example, If I wanted to sample random values from an exponential distribution with $\lambda = 1$, I can do uniform_to_pdf(rand_eca(1e5, 1), @(x) exp(-x), 0, 6, 10000) which produced the third plot in Figure 4.

5

5 Conclusion

In this paper I have implemented a random uniform function called `rand_eca` in Matlab by iterating Elementary Cellular Automata rule 30. I have also implemented a function called `uniform_to_pdf` that transforms the uniform sampling to any other probability density function.

All the functions are open source at https://github.com/xnought/rand-eca. If you would like to reproduce the figures and statistical tests from this paper, see the `paper_figures.mlx` file.
